

Bryan Kim Calipes
BSIT 3

1. What concept challenged you the most, and why?
 - The concept that challenged me the most is encryption. I found it hard to understand how data becomes unreadable and then goes back to normal again. The different types of encryption algorithms also confused me at first. I had to read the topic many times just to understand how keys work. But even if it was difficult, I know it is very important for securing data.
2. Which threat, vulnerability, or countermeasure is most important for your future career?
 - I think the most important is authentication and strong password security. As a future IT professional, I know many systems fail because users still use weak or repeated passwords. This makes systems easy to attack even if the technology is strong. Learning how to enforce strong authentication can protect both users and organizations. This is important because security always starts with controlling who can access the system.
3. What security principle would you apply to your daily digital life, and why?
 - I would apply multi-factor authentication to my daily digital activities. It adds an extra layer of protection to my accounts. Even if someone steals my password, they still cannot enter without the second verification. This reduces the chance of hackers accessing my personal information. Using MFA makes me feel safer and more responsible in managing my digital security.
